## Resource pack

Everything you need, and where it already is. Nothing here has to be downloaded or installed: your machine arrives with all of it in place.

# 1 Your machine

Each team gets a cloud instance with a Tenstorrent Wormhole n150 card in it, reached through a browser. There is nothing to install and no account to create, and it stays alive for the whole event.

**Access details are handed out at the start of the hackathon, on the day. Until then there is nothing for you to set up.**

# 2 What is already on it

| Where | What it is |
|---|---|
| ~/challenge/README.md | The one document that covers everything: the detector, the measurements, the two thresholds you choose, how you are scored, and the two traps that have already cost us a day each. Read this first. |
| ~/challenge/harness/ | The tool that scores you, in your hands from the first hour. A template to copy and fill in, the interface it expects, a worked answer, and a plotting tool for your trade-off curve. See harness/README.md. |
| ~/challenge/bench/ | Measurement. run_bench.sh times one frame stage by stage, run_levers.sh shows what each change is worth on its own, run_loop.sh measures the whole frame on the fast path. See bench/README.md. |
| ~/challenge/practice/ | 200 photographs with their answers recorded. Not the ones you are scored on and they do not overlap. Tune against them as hard as you like. |
| ~/challenge/sample/ | Two photographs, so you can prove your submission is the right shape on day one in seconds. See sample/README.md. |
| ~/challenge/data/ | The raw output behind every number we quote, with the board, firmware and software version recorded beside it. Diff your runs against ours. See data/README.md. |
| ~/challenge/webcam_demo/ | A live camera demonstration for your pitch: your laptop camera, detection running on the card. See webcam_demo/README.md. |
| ~/challenge/setup/ | How the detector was put on the machine, kept so you can see what was done rather than guess. |
| ~/tt-metal/ | The framework and the detector source, already built and ready to run. |

All six README files travel with the machine and are readable offline, so you are never dependent on the venue network to find out how something works.

# 3 The first three commands

- cat ~/challenge/README.md — start here, before touching anything else
- cd ~/challenge/bench && bash run_bench.sh — your own machine's starting measurement, which you will need at hand-in
- cp ~/challenge/harness/submission_template.py ~/challenge/my_submission.py — the file you will edit for thirty hours

# 4 Help, while you work

| Where | What for |
|---|---|
| Three Tenstorrent engineers, on site | All three days. Ask early rather than losing a day to something one of us has already hit. |
| docs.tenstorrent.com | The framework documentation: TT-Metalium and TT-NN, the programming model, and the operations the detector is built from. |
| discord.gg/tenstorrent | The developer community, for questions that outlive the hackathon. |
| Claude API credits | Every participant receives $100 in credits from the organisers, so you do not need to bring your own licence. |

# 5 What you hand in

The two-page challenge briefing has the full list. In short: your submission file, a one-page log of what you changed and what each change was worth, the settings you chose, your starting measurement, and the result files behind your curve. Sixty per cent of the mark is the result, forty per cent is how well you explain it.
